PCT/GB01/05297

IMPROVED METERING VALVE AND ACTUATOR FOR METERED DOSE INHALER

The present invention relates to a metered dose inhaler for delivering a metered amount of a formulation from a pressurized canister carrying a metering valve in which spray producing mesos are located in the metering valve, in particular in the valve stem of the metering valve, rather than in the actuator.

Purtable devices are widely available to a patients wishing to self-administer therapeutic and preventative medicament formulations to combat the symptoms of respiratory disorders, such as authora. Such devices are generally arranged to dispense a discrete amount of the formulation, (usually in the form of a finid or particulate medicament entrained in a stream of gas or vapour) into the respiratory passages and are widely referred to as metered dose inhalers.

Typically, a metered dose inhalor comprises two main parts, namely a canister containing the pressurized framulation and an actuator device baving a month piece for delivering the metered amount of formulation to the user.

In general, a metered dose inhaler comprises a cylindrical housing which receives a cylindrical canister containing a pressurized medicament formulation. The canister is provided with a dispensing metating valve including a metering chamber and a valve atom having an internal conduit which makes a tight push fit engagement into a valve stem block located towards the end portion of the cylindrical housing and adjacent the mouth piece simuted at the end of the semator.

To activate the metered does inhales, the case applies a compressive facts to the closed end of the conjects. The internal components of the metering

> valve are spring-loaded so that a low compressive force is sufficient for the canister to move axially with respect to the valve stem by an amount sufficient for the valve stem to penetrate the emister and cause a metered quantity of formulation to be expelled through a single transfer port (of diameter about 0.6mm) into the internal conduit of the valve stem which cases with an internal cavity in the valve stem block which generally includes a large sump. The formulation flows from the sump via a channel into a cone-shaped spray nozzle situated in the valve stem block and thereafter into the mouth piece of the actuator, whereby a user inhaling through the mouth piece will receive a metered dose of medicament containing formulation. There is therefore defined a non-uniform flow path of large volume between the discharge part of valve stem and the mouth piece. In particular, it should be noted that the valve stem block contains a stray-producing means in the form of the conical cozzle (1).

When a metered dose inhaler is operated in this manner, the propellent formulation undergoes rapid initial expansion at atmospheric pressure into the relatively large volume of the internal cavities of the valve street end of the valve stem block to produce a range of different sizes of propellent droplets containing the medicament either in autpention or in solution. Although the number of large droplets decreases over time, the user tends to inhale a mixture of small and large droplets. Whilst small droplets tend to exert the desired therapeutic effect, large droplets are known to deposit undesirably in certain bodily regions where they may lead to localized side effects. Similar considerations apply in relation to dry powder metered dose inhalms where there is a risk that larger powder particles will deposit in the upper air ways, rather than the fine branches of the Iring, underirable bodily

15

20

25

In order to alleviate this effect, the dismeter of the channel linked to the query nousie in conventional meterod done inhalters in generally low except to create a constriction or buildeneck in the non-uniform flow path. Typically, the channel is 0.22mm or less in discusive so as to impose primary 10

WO 8243794

Bow coursel and provens the undesirable accumulation of larger droplets/particles. This narrow channel has the added benefit that the droplets/particles do not pass too quickly into the users mouth.

A disadvantage of imposing primary flow control in this manner is that the channel is prone to blockage. For example, it has been found that in dispensing Salbutamol HFA (which is a suspension of Salbutamol in P134s containing about 10% otherwill be medicament accumulates at on near to the entrance and cart and of the channel. As well as the inconvenience to the user, the build-up of material leads to a reduction in the effective does dispensed. This effective does can drop significantly over the lifetime of the matered does imhaler (typically 2000 to 300 doess).

The present invention seeks to improve delivery of a pressurized farmulation from a metered dose inhaler by locating spray-producing encess in the flow path at or near to the outlet of the pressurized continer, rather than in the actuator. More particularly, the spray-producing means are located at or near to the outlet of the pressurized consister by having spray-producing means, e.g. in the form of a spray onifice, in the valve stem. The advantage to the user is that a softer spray of a formulation of improved quality is achievable without increasing the risk of blockuper.

According to the invention, there is provided an acrosol inhalation device, comprising an actuator, canister containing pressurized acrossol formulation received in said actuator, the emister having a dispensing metering valve comprising a metering chamber, a valve stem disposed therein and movable between a charge position, in which the chamber is isolated from the atmosphere whilst the chamber communicates with the interior of the canister, and a discharge position, in which the contents of the chamber can be discharged to the atmosphere whilst the chamber is isolated from the canister, the valve stem having at least one transfer port, adapted to communicate with the chamber in the discharge position and a discharge port, adapted to engage valve stem location means in the accustor having a

WO 82/43794

in an alternative embodiment, a transfer port may act as the spray-producing means, provided that it is sufficiently small to restrict the flow of formulation from the presunized emister.

PCT/GB01/05197

When more than one transfer port acts as the spray-producing means, there are preferably at least two transfer ports arranged in a substantially common radial plane of the valve stem. In this alternative embodiment, there are preferably two transfer ports substantially diametrically opposed to one mother. If there are more than two transfer ports, they are preferably arranged symmetrically so that the flow of formulation is mixed in the center of the flow conclusion of the stem.

Preferably, the internal conduit of the valve stem tapers uniformly and inwardly from the cod portion bearing the discharge port to the portion bearing the treasfer port, for ease of modeling. In this embodiment, the internal conduit may be essentially conical (e.g. a truncated cone). The diameter of the outermost bore (y) is preferably between x and 10x (where x is the diameter of the internoot bore).

Preferably, the diameter of the immemoral bore (x) is 80% or less of the diameter of the outermost bore (y). Particularly preferably, the diameter of the immemoral bore (x) is in the range of 40 to 80% of the diameter of the outermost bore (y).

Typically, when the transfer ports in the valve stem function as the quayproducing means they have a diameter of 0.12mm or more. In general, effect sprays are produced when the diameter is less than 0.4mm.

Typically, the valve stem location means is in the form of a valve stem block provided with a valve stem location portion, in which the valve stem makes a tight fit expansess and a dispensing portion, which is extraged to dispense stemined fortunation to the user. flow connection with the atmosphere, the stem including a flow conduit linking the at test one transfer port with the discharge port, such that the valve stem and the valve stem location metus cooperate to form a continuous flow path, characterized in that the stem includes spray-producing means.

Although the introduction of spray-producing means into the valve stem might have been expected to allow the formulation to exhaust more rapidly and therefore to add to the problems of blocking etc., it has been found that that this is not so. A spray orifice located in the flow path at or near to the crit end of the pressurized canister eliminates the nood for a narrow diameter channel in the valve stem block and permits a larger diameter discharge spermer in the valve stem block than might otherwise been have expected for this type of samplement.

The spray-producing means may be in the form of a spray orifice located close to the transfer port of the valve stem, and in the flow path defined by the valve stem and the valve stem location means. In such an arrangement, the one or more transfer ports in the valve stem communicate with the spray crifice by means of a spray chunnel of substantially smaller diameter to the internal flow conduit of the valve item. This channel may be, for example, tess than 0.3mm, such as 0.2mm in diameter, so as to break up the pressurized liquid formulation into droplets. The valve stem may be provided with more than one transfer port, e.g. two, substantially diametrically opposed to one mother. Preferably, when there is more than one sperture, the spectures are arranged in a substantially common radial plane of the valve stem. If there are more than two transfer ports, they are preferably arranged symmetrically so that the flow of formulation (which may be suspended or dissolved in the liquefied propellant) is effectively in the center of the flow path of the valve stem.

When the spray-producing means are located in the valve stem and experate form the transfer ports, the external sperture size transfer ports may be of conventional dimensions, (e.g. having a diameter of about 0.6mm).

90 02/3794 PCT/GB01/65297

Typically, the valve stem engagement portion and the discharge portion are linked by a flow path which has a diameter greater than 0.22mm, (for example, 0.5-2mm).

The flow channel in the valve stam location means may form an L-chaped flow path with the valve stam. In general, the two limbs of such an L-chaped flow path are at an angle of greater than 90°, e.g. shout 115°. However, the two limbs of the flow path may be at an angle as great as 135° or morn. The flow path defined by the valve stam and the valve location means need not be angled, and it is possible to have the flow path defined by the valve stam location means which is straight line.

Preferably the cavity in the valve stem contains a shoulder upon which a pursion of the wall at the first end of the valve stem is supported. Preferably the supported portion of the wall at the first end of the valve stem is a portion farthest away from the spray producing means.

Preferably the actuator device is provided with a delivery ocales adapted to defiver the discrete amount of faramatoion to the user, said defivery outlet being in third communication with the dispensing portion of the valve stem location means. The outlet may be adapted for usual delivery or preferably, with a mountapines for oral delivery to the image, wis the pharyne.

25 The dispensing portion of the valve stem location means may take my convenient things such as a V-shape. In order to prevent repid expansion and solid deposition on the walls of the dispensing portion, alternative thapes may be used such as W-shapes. Preferably the dispensing portion has curved intensal walls to define a knooth flow path.

According to a further expect of the invention, we further provide a valve stem as hereinbefore defined.

41 %

15

30

25

30

According to the invention, we further provide an actinator for one in association with a pressurized container having a metering valve as hereinhefore defined. Preferably, the actuative comprises a valve stem location means capable of engaging a valve stem of a pressurized container such that the valve stem and the valve stem not a continuous flow path.

In general, the methods for manufacturing the components parts of the invention will be familiar to those skilled in the srt. For example, injection moulding may be used to make the valve stem. In general, the internal conduit of the valve stem will be larger than the internal conduit of conventional valve stems of this invention. When the spray-producing means is combined with the transfer ports, the internal conduits of the transfer ports will generally be smaller relative to those described in the prior art, which will necessitate the use of smaller dismeters side pins. In contrast, the moulding stem pin will generally be larger than used relative to the prior art. During injection, two supporting side pins may be used to grip the stem pin whils forming twin spertures. The stem and side pins are made from any suitable material such as stocl.

The metered dose inhaler of the invention may be of the manually operable or breath actuated type. It is envisaged that the invention may be used primarily in conjunction with the delivery of a medicancent in the form of a propellant solution, dispersion or (preferably) suspension or in the form of a dry powder. It is thought that pulmonery inhalation would be the primary application of the invention either usually or (preferably) orally and the delivery outlet of the actuatior device may be adopted accountingly.

By way of example only, the present invention could be used to deliver medicaments including antiallergies, analysics, broochodilators, antihistamines, therapeutic proteins and peptides, antimatives, engined preparations, antibiotics, auti-inflammatory preparations, hormones, or sulfommides (such as for example a vasconstrictive amine, as enzyme, as

WO 02/4794 PCT/GB01/05297

generally cylindrical bousing (1) having a month piece (2) angled at about 115° to the perpendicular axis of the cylindrical bousing (1). The bousing (1) receives a cylindrical caminter (3) of pressurized medicament, the caminter (3) being provided at one end with a matering valve including a valve stam (4). The valve stam (4) is located in, by means of a tight fit engagement, in a cavity in a valve stam location means in the form of a valve stam block (5) extending upwardly from the closed base of the cylindrical bousing (1). In addition to a recognism cavity (6), which engages with the valve stam (4), the valve stam block (5) excluses a channel (7) communicating with the reception cavity (6) and terminating in a discharge cut opposite the mouth piece (2), such that the valve stam (4) and the valve stam block (5) corporate to form a generally L-shaped continuous flow path. The discharge cut (8) of channel (7) is topers putwarth with respect to the overall cross-section of channel (7), and typically is of a distinuter in the range (3-2 am.)

Valve stem (4) has a substantially cylindrical main body with a pair of dismetrically disposed transfer ports (9,10) located edjacent to and just outside the consister (3), when the consister is in the charge position. The valve stem (4) excloses a smilormly topering internal conduit (11) extraording, at its nurrow end, from the region of the transfer ports (9,10) and terminating with the discharge port (12) of the valve stem, which is located in the valve stem block (5). The discarge end portion of the valve stem (4) is partially sected on an internal shoulder (11) in the reception cavity (6).

The transfer ports (9,10) are in the form of cylindrical sportures in the outer surface of the valve stem (4), such transfer port after an initially cylindrical cross-section topers down to cylindrical channels (14,15) in moving towards the center of the valve stem, the ports (9,10) and channels (14,15) sering as a spray-producing means in the form of opposed spray orifices. The ports (9,10) channels (14,15) internal conduit (11) and stem block channel (7) cooperate to form a continuous flow path.

Asial movement of the carriers (3) relative to the valve atom 4 and towards

alkaloid, or a steroid and synergistic combinations of these). Examples of medicaments which may be employed are: Isoproterenel [abpha [isopropylaminomethyl]] protocatechnyl alcohol], phenyleptrine, phenylptropanolamine, gheagen, adrenochrome, typein, cyincephrine, ephedrine, narrotine, coderine, atropine, beparin, morphine, chlyptrocarphinone, ergotamine, acopolamine, methapyrilene, cyanocobalamin, tarbutaline, rimiterol, salbutamol, firmisolide, colchicine, pirbuterol, beclomethasone, orchrenaline, fentsoyl, and diamorphine. Others are ambitotics (such as neonycin, streptomycin, penicillin, procesine penicillin, tetracycline, chlorotetracycline and hydroxytextracycline), administratory is bermones and administration hormones (such as contisione, bydrocartisone acctate and profinisolone), insulin and amiallergy compounds (such as cromely) asolium).

20

In a preferred embodiment of the metered dose inhalter of the invention, the formulation comprises: salbutamol together with a propellent and optionally one or more additives. Particularly preferably the formulation comprises salbutamol and PI34a (especially preferably with about 10w1% chanol).

20 Preferred embediments of the device according to the invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a partially truncated vertical section of an acrosol actuator according to the invention fitted with a pressurized medicament camister;

Figure 2 is a metering valve according to the invention, shown in vertical section and:

30 Figure 3 are alternative embodiments of valve stems according to the invention, shown in partially truncated vertical section.

Referring first to Figure 1, an acrosol inhalation actuator comprises a

WO 82/4794 PCT/GB01/6527

the stem block (5) permits transfer ports (9,10) to easier the metering valve in the emister (3). A metered amount of presumized formulation passes through ports (9,10) and into the innormost ends of the channels (14,15) in the valve stem (4). The two streams of formulation are strained and interfere to such an extent that the combined flow is slowed relative to its initial velocity. The formulation passes out of the discharge exit (8) in the valve stem block and delivers the formulation through the mouth piece (2) to the user.

Referring now to Figure 2, a metering valve according to the invention comprises a body in the form of a circular cup (21) fitted in a ferrular (22). A valve butch (23) provided with an apertumer base fits in the cup (21) defining a metering chamber (24) which is fixed with respect to the cup (21). The metering chamber (24) is provided at the outer end, immediately adjusted to the field (22) with an outer seal or gather (25), and at the inner end with an immer seal or gather (26). The inner end of the chamber (24) is adapted to fit within the interior of a pressurized acrossol canisar.

A hollow tubular guide (27) extends from the cup 20 beneath the chamber (24) and inner seal (26). The side walls of the guide (27) are additionally provided with diametrically opposed elonguic speratures (not shown). The lower end portion of the guide (27) is provided with an inwardly facing peripheral flange (25).

A valve member in the form of a valve stem (29) of generally circular crosssection extends through the chamber (24) and into the interior of the gride
(27). The end portion of the valve stem extending into the gride (27) is
sturveneded by a compression spring (30), retained in the gride (27) by the
flange (21), and bearing against an attentive coller (31) mounted on the inner
coll parties of the valve stem (29). The coller (31) is sliciably mounted
within the gride (27).

The spring (30) erges the valve stom (29) towards the inoperative position

5

10

WQ 02/43794 PCT7G390/46297

shown in Figure 2. The outwards movement of the valve stem (29) is limited by a peripheral in (12) extending from the stem (29) within the metering chamber (24), which bears against the outer sent (23) when the valve is in the inoperative position. The rib (32) shao limin the inwards movement of the valve stem (29) by bearing against the base of the bush (23) when the valve stem is in the operative (discharge) position.

The lower portion of the valve stem (29) is provided with mexes for the communicating the chember (24) with the interior in the form of a pharality of chemels (33) when the valve stem (29) is in the inoperative position. The chembel (33) are arranged such that when the stem (29) is in the inoperative position, they terminate just above the inner seal (26), within the base of the buth (23). A small annular space, (34), e.g. of about 0.2mm width, provided in the base of the buth (23) and surrounding the valve member (29), comment to communication between the chamber (24) and the interior is established by the chambel (33) when the valve stem (29) is in the inoperative position.

The outer end portion of the valve stem (29) is provided with an outlet conduit (13) through which a charge can be dispensed from the metering chamber (24), such charge entering the outlet conduit (15) through diametrically opposed transfer ports (36, 37) located on the valve stem (29) and lying outside the metering chamber (24) when the valve is in the imperative (charge) position (as shown). The entrance of the transfer ports in the outer wall of the valve stem (29) are cylindrical in cross-section, but on moving towards the center of the valve stem taper towards spray channels (38, 39) which, with the tapered portion of the transfer ports (36, 37) function as spray-producing means. The transfer ports (36, 37), channels (34, 39), and internal conduit (35) form a continuous flow path through which a charge can be dispensed from the metering chamber (24), such charge extering the outlet conduit (35) via the transfer ports (36, 37). In the inoperative (charge) position, the transfer ports (36, 37), in the compensative (charge) position, the transfer ports (36, 37). In the inoperative (charge) position, the transfer ports (36, 37), in the commission with the chamber (24), no inward movement of the stem

WO 02/43794 PCT/GB01/05297

radially disposed towards the opposing end of the stem. A spray nozzle
formed from a cylindrical channel (55) disposed on the vertical axis of the
valve stem and a cone (56) communicate with the transfer port (54) and the
internal conduit (52) to form a continuous flow path.

Figure 3(b) Illustrates a valve which is similar to that illustrated in Figure 3(a) save that two transfer ports (57, 58) are dismetrically disposed across avalve stem (59), to firm a single through pring channel. A spray nozzle formed from a cylindrical channel (60) disposed on the vertical axis of the valve stem and a cone (61) communicate with the transfer port (54) and the internal conduit (52) to firm a continuous flow pach.

Figure 3(c) is a vertical section through the valve stem of Figure 3A along

In figure 3(d), spray-producing means are formed in a valve stem (62) having an internal conduit (63), by having radially disposed transfer ports (64, 65) which intersect with the non-discharge portion of the internal conduit, in use, a metered uncount of formulation passes through transfer ports (64,65) into the intermost end of the tapered internal conduit (63) of the valve stem(62). The two streams of formulation interfars to such as extint that a quay is produced in the region of the non-discharge portion (66) of the conduit (63).

WO 02/13794 PCT/GB01/05/297

(29) to the operative (discharge) position.

The stem (29) forms a scaling fit with the outer scal (25) in both the operative and inoperative positions, and a scaling fit with inner scal (26) only when the valve is in the operative position.

Thus, in the imperative position, the chamber (24) is scaled from the outside (the atmosphere), but is adapted to communicate with the interior of the container, and in the operative position communicates with the outside, while being scaled from the interior.

In use, the valve is crimped onto a cylindrical expister for pressurized serosol material, eg a modicament formulation, the container bearing against the container gestert (40). In the inoperative position, the pressurized material can readily move from the chamber (24) to the interior of the container, and vice versa, by means of the chambel (33).

With the valve inverted, is with the outer dispensing portion of the valve stem (29) pointing downwards, the chamber fills with pressurized liquid propellant. Actuation of the valve stem (29), against the bias of the spring (30), causes the transfer ports (36, 37) to move into the chamber (24), allowing pressurized material to be dispensed from the chamber (24) via the internal conduit (35) to the outside.

in Figure 3, alternative embodiments of the valve stem are illustrated. In Figure 3(a), a valve stem (51) is provided with an internal condmit (52) connecting the discharge end of the stem (53) with a transfer port (54)
